Mathias Verras
@mathiasverraes

There are only two hard problems in distributed systems: 2. Exactly-once delivery 1. Guaranteed order of messages 2. Exactly-once delivery

Lecture Goal: Balance a healthy love-hate relationship with distributed systems

Previously in CSSE6400...

Service-based Architecture

Re-visiting service-based architectures from last lecture

Simplicity For a distributed system

Reliability Independent services

Scalability Coarse-grained services

Let's revisit these attributes

Previously in CSSE6400...

Simplicity *For a distributed system*

This condition is doing a lot of work

Simplicity

We'll look at a few reasons that distributed systems are *fundamentally* quite challenging

Question

What is a *fallacy*?

Definition 1. Fallacy

Something that is believed or assumed to be true but is not.

A few reasons for complexity

The Fallacies of *Distributed Computing*

Sun Microsystems in 1994, primarily accredited to Peter Deutsch
(doy-ch)

Fallacy #1

The network is reliable

Solve it by resending it

If the service goes down and all clients are re-trying, the service is in for a shock when it comes back, we solve this with *exponential backoff*

Exponential backoff

```
1  retry = True
2  do:
3      status = service.request()
5
5      if status != SUCCESS:
6          wait(2 ** retries)
7      else:
8          retry = False
9  while (retry and retries < MAX_RETIRES)
```

Causes duplicate actions, problem for ordering/payments

Use tokens to prevent duplicates.

Fallacy #2

Latency is zero

Network Statistics

Home to UQ

Home to us-east-1

EC2 to EC2

Network Statistics

Home to UQ 20.025ms

Home to us-east-1

EC2 to EC2

Network Statistics

Home to UQ 20.025ms

Home to us-east-1 249.296ms

EC2 to EC2

Network Statistics

Home to UQ 20.025ms

Home to us-east-1 249.296ms

EC2 to EC2 0.662ms

Be mindful when designing distributed systems. Network call much slower than local call.

Fallacy #3

Bandwidth is infinite

Similar to previous fallacy, be mindful, distributed calls clog up network.

Fallacy #4

The network is secure

Authentication only occurs when entering Sahara data centre

Bad actor gets access via one insecure node, network is compromised. Practice defence in depth.

Fallacy #5

The topology never changes

Topology changes all the time, cloud has just made this easier.
Don't rely on static IPs. Don't assume consistent latency.

Fallacy #6

There is only one administrator

Scenario

- Deployments are banned on the weekend.

Scenario

- Deployments are banned on the weekend.
- Sunday night users start complaining.

Scenario

- Deployments are banned on the weekend.
- Sunday night users start complaining.
- There have been no deployments since Friday.

Scenario

- Deployments are banned on the weekend.
- Sunday night users start complaining.
- There have been no deployments since Friday.
- You can still access the system.

Scenario

- Deployments are banned on the weekend.
- Sunday night users start complaining.
- There have been no deployments since Friday.
- You can still access the system.
- Who do you talk to?

Things spontaneously break. Who can help you?

Fallacy #7

Transport cost is zero

Remember

Distributed systems are *hard*.

Remember

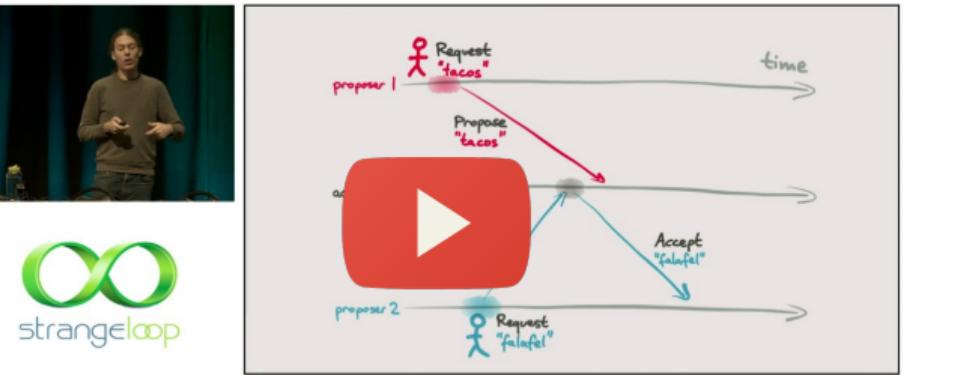

Distributed systems are often *not your friend.*

Can often introduce more problems than they solve

When you need to, prove it

Reliability Independent services

Question

What makes software *reliable*?

Perhaps software that always works?

'Working' software

Satisfies the functional requirements

Definition 2. Reliable Software

Continues to work, even when things go wrong.

Definition 3. Fault

Something goes wrong.

Death, taxes, and computer system failure are all inevitable to some degree.

Plan for the event.

- Howard and LeBlanc

Reliable software is

Fault *tolerant*

John von Neumann built fault tolerant hardware in the 50s.

Problem

Individual computers fail *all the time*

10-50 years hard-drive lifetime. 10,000 disks will fail daily.

Solution

Spread the risk of faults over *multiple computers*

Spreading Risk

If you have software that works with *just one* computer, spreading the software over *two* computers *halves* the risk that your software will fail.

Spreading Risk

If you have software that works with *just one* computer, spreading the software over *two* computers *halves* the risk that your software will fail.

Adding *100* computers reduces the cuts the risk by *100*.

Spreading Risk

If you have software that works with *just one* computer, spreading the software over *two* computers *halves* the risk that your software will fail.

Adding *100* computers reduces the risk by *100*.

Of course, there are other reasons you might want run software on multiple computers.

- Why is this software somewhat reliable?
- Any individual service can go down and the rest still work.
- Can we do better?
- Can a service go down but have that service still work?

Scalability Coarse-grained services

Question

Who has used *auto-scaling*?

Auto-scaling Terminology

Auto-scaling group A *collection of instances* managed by auto-scaling.

Auto-scaling Terminology

Auto-scaling group A *collection of instances* managed by auto-scaling.

Capacity Amount of instances *currently* in an auto-scaling group.

Auto-scaling Terminology

Auto-scaling group A *collection of instances* managed by auto-scaling.

Capacity Amount of instances *currently* in an auto-scaling group.

Desired Capacity Amount of instances *we want to have* in an auto-scaling group.

Auto-scaling Terminology

Auto-scaling group A *collection of instances* managed by auto-scaling.

Capacity Amount of instances *currently* in an auto-scaling group.

Desired Capacity Amount of instances *we want to have* in an auto-scaling group.

Scaling Policy How to determine the desired capacity.

Auto-scaling Terminology

Auto-scaling group A *collection of instances* managed by auto-scaling.

Capacity Amount of instances *currently* in an auto-scaling group.

Desired Capacity Amount of instances *we want to have* in an auto-scaling group.

Scaling Policy How to determine the desired capacity.

Minimum/Maximum Capacity *Hard limits* on the minimal and maximum amount of instances.

What we really want

Desired Capacity Amount of *healthy* instances we want to have in
an auto-scaling group.

Health check

User defined method to determine whether an instance is *healthy*.

Auto-scaling

An example

Product service keeps going down

We might expect product service to have a much higher load than other services

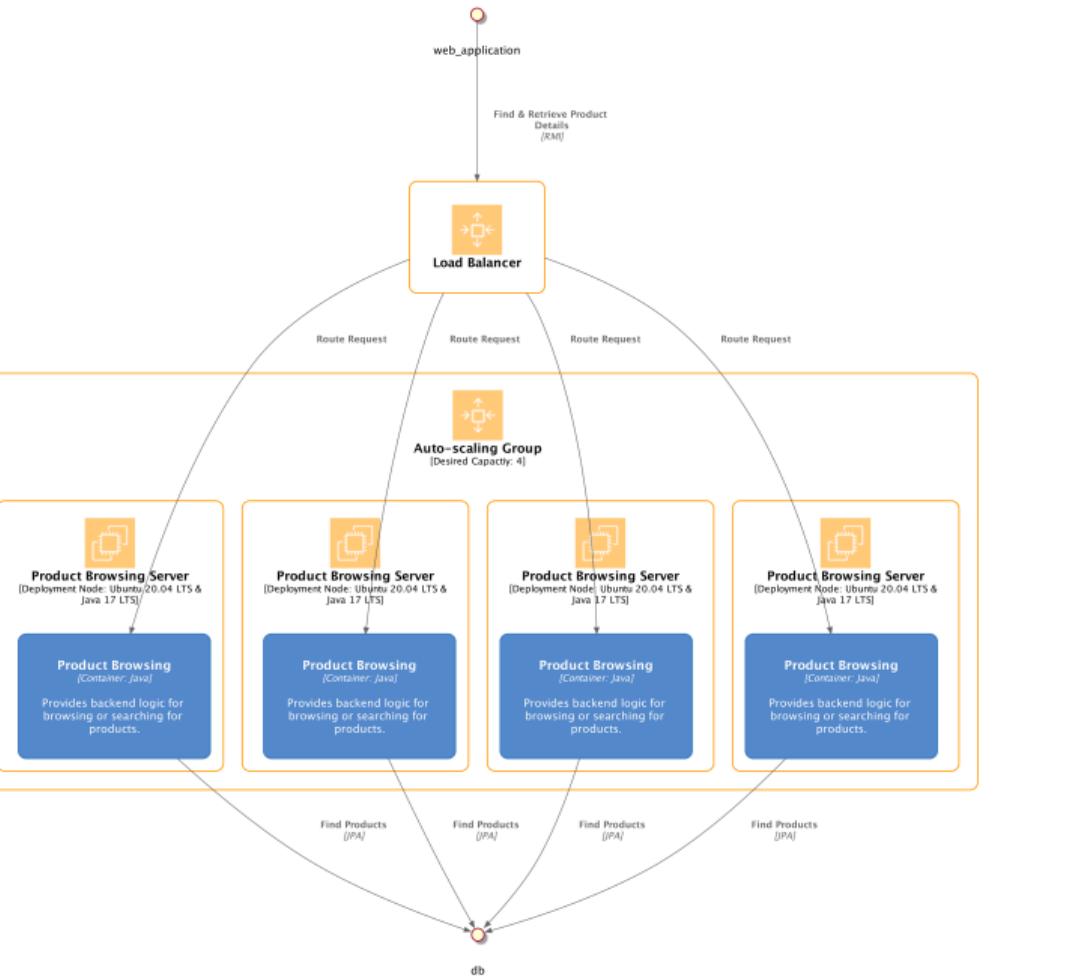

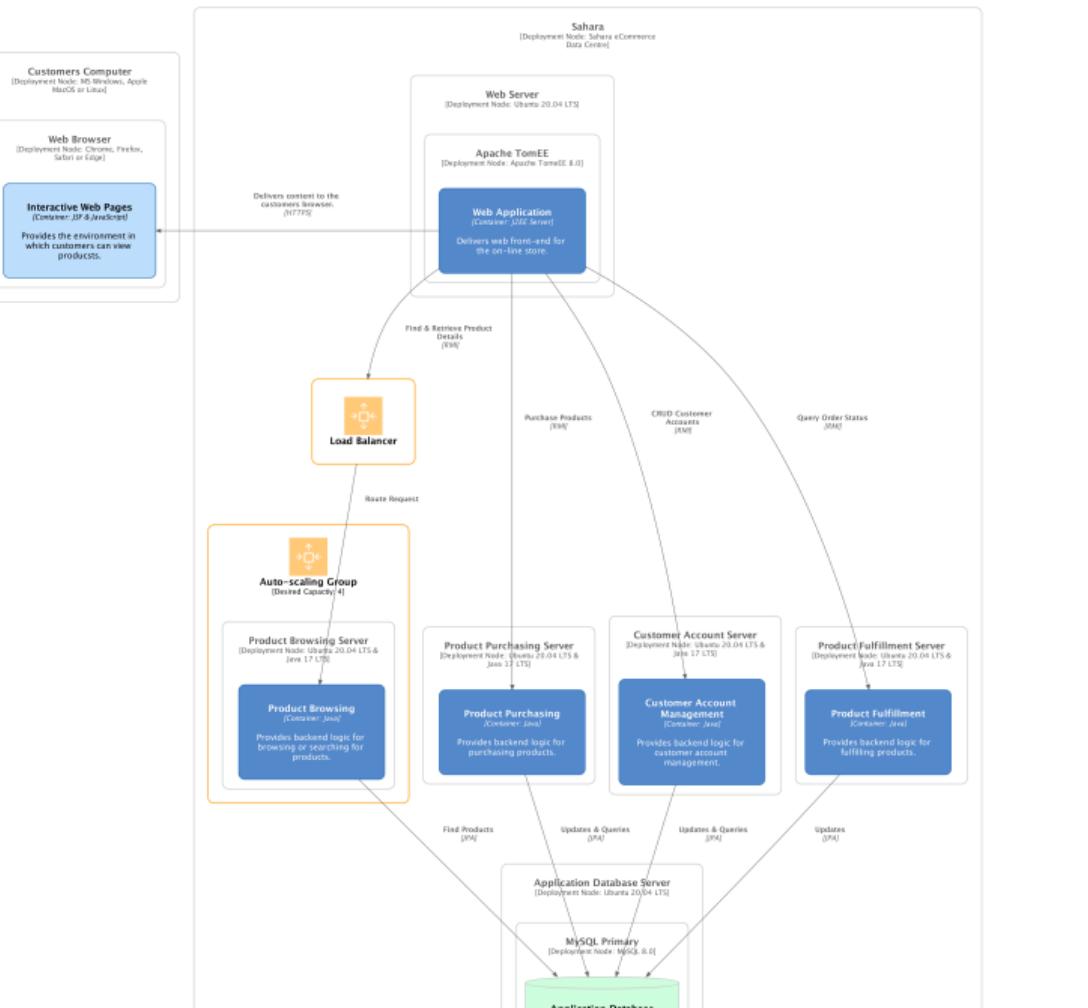

Use an auto-scaling group to replicate the service

What's the problem?

Traffic was all sent through the one instance, load balancer routes to all

In Summary

Simplicity

Reliability

Scalability

In Summary

Simplicity *Minimal network communication* (compared to other distributed systems), less impacted by fallacies.

Reliability

Scalability

In Summary

Simplicity *Minimal network communication* (compared to other distributed systems), less impacted by fallacies.

Reliability Traffic is spread to various services, still *partially operational* if one goes down. Auto-scaling allows for *basic replication*.

Scalability

In Summary

Simplicity *Minimal network communication* (compared to other distributed systems), less impacted by fallacies.

Reliability Traffic is spread to various services, still *partially operational* if one goes down. Auto-scaling allows for *basic replication*.

Scalability Auto-scaling and load balancing allows *individual services to scale*. However, the *database is a bottle-neck*.

database is a bottle-neck is foreshadowing
